Water supply

- 4 villages are supplied with water by 3 water towers
- Each water tower has a maximum rate of flow expressed in L/s
- Each village expresses preferential needs in L/s
- Various pipes exist between water towers and villages, whose current capacities and uses are known

Water supply

- 1 Modelize the transport network. What is the value of the flow?
- 2 Determine the maximum flow.
- 3 Formulate the possible additions to meet the minimum requirements.

Transport network and flow value

- Adding virtuals source and sink

Transport network and flow value

- Capacities related to the problem values

Transport network and flow value

- Flow calculated by Kirchhoff's law

Transport network and flow value

- Flow calculated by Kirchhoff's law
- $\varphi = 80$

Maximum flow

Maximum flow

Maximum flow

- Augmenting path (S, A, E, B, D, P)

Maximum flow

- Augmenting path (S, A, E, B, D, P) : $\delta = 5$

Maximum flow

- No more augmenting path

Maximum flow

- Maximum flow: $\varphi = 85$

Minimum possible additions

Adding an arc with a capacity of 5 on one of the three paths:

- (A, B)
- (A, D)
- (E, D)

Conclusions

- The initial flow is $\varphi = 80$
- The maximum flow is $\varphi = 85$
- The validation of preferential needs can't be achieved without changing the network
- 3 optimal amendments are identified
